## ABOUT DEPRESSION

The PROMIS Depression item banks assess self-reported negative mood (sadness, guilt), views of self (self-criticism, worthlessness), and social cognition (loneliness, interpersonal alienation), as well as decreased positive affect and engagement (loss of interest, meaning, and purpose). Somatic symptoms (changes in appetite, sleeping patterns) are not included, which eliminates consideration of these items’ confounding effects when assessing patients with comorbid physical conditions. The depression short forms are universal rather than disease-specific. All assess depression over the past seven days.

The PROMIS Pediatric and Parent Proxy Depression item banks assess negative mood (sadness, guilt), views of self (self-criticism, worthlessness), and social cognition (loneliness, interpersonal alienation), as well as decreased positive affect and engagement (loss of interest, meaning, and purpose).

The PROMIS Early Childhood Parent-Report Depressive Symptoms item bank assesses sadness/withdrawal, negative views of self (self-criticism, worthlessness, low self-esteem), and anhedonia (loss of interest, inability to engage in play, lack of enjoyment).

Depression instruments are available for adults (ages 18+), pediatric self-report (ages 8-17) and for parents serving as proxy reporters for their child (youth ages 5-17) or very young child (ages 1-5).
INTRODUCTION TO ASSESSMENT OPTIONS

There are two administration options for assessing depression: short forms and computer adaptive test (CAT). When administering a short form, instruct participants to answer all of the items (i.e., questions or statements) presented. With a CAT, participant responses guide the system’s choice of subsequent items from the full item bank (28 items in total for adults). Although items differ across respondents taking a CAT, scores are comparable across participants.

Some administrators may prefer to ask the same question of all respondents or of the same respondent over time, to enable a more direct comparability across people or time. In these cases, or when paper administration is preferred, a short form would be more desirable than a CAT. This guide provides information on all depression short form and CAT instruments.

CAT: A minimum number of items (e.g., 4) must be answered in order to receive a score for Depression CATs. The response to the first item will guide the system’s choice of the next item for the participant. The participant’s response to the second item will dictate the selection of the following question, and so on. As additional items are administered, the potential for error is reduced and confidence in the respondent’s score increases. CAT will continue until either the standard error drops below a specified level (e.g., on the T-score metric 3.0), or the participant has answered the maximum number of questions (e.g., 12), whichever occurs first. For some CATs, specifically “recommended” and “screen-to-CAT” there are additional stopping rules. These include stopping when the standard error isn’t improving much or if a respondent is asymptomatic. For details on the exact stopping rules for Depression CATs, see below.

CAT versus Short Form: Whether one uses a short form or CAT, the score metric is Item Response Theory (IRT), a family of statistical models that link individual questions to a presumed underlying trait or concept of depression represented by all items in the item bank. When choosing between a CAT and short form, it is useful to consider the demands of computer-based assessment, and the psychological, physical, and cognitive burden placed on respondents as a result of the number of questions asked.

Figure 1 illustrates the correlations (strength of relationship) of the full bank with a CAT and with short forms of varying length. The correlation of CAT scores with the full bank score is greater than a short form of any length. A longer CAT or longer short form offers greater correlation, as well as greater precision. When evaluating precision, not all questions are equally informative. The flexibility of a CAT to choose more informative questions offers more precision.

VERSION DIFFERENCES

Some PROMIS domains have multiple versions of instruments (i.e. v1.0, v1.1, v2.0). Generally, it is recommended that you use the most recent version available which can be identified as the instrument with the highest version number. In most cases, an instrument that has a decimal increase (v1.0 to v1.1) retains the same item-level parameters as well as instrument reliability and validity. In cases where a version number increases by a whole number (e.g., v1.0 to v2.0), the changes to the instrument are more substantial.
Adult

**Standard, Recommended, and Screen-to-CAT Stopping Rules:** The standard, recommended, and screen-to-CAT Adult Depression computer adaptive tests are based on the exact same item banks, but utilize different stopping rules. The PROMIS Bank v1.0 – Depression measure is administered by default as computer adaptive tests using the following standard stopping rules:

- Minimum number of items administered = 4
- Stop when one of these occurs:
  - 12 items are administered OR
  - Standard error is below 0.3 on the theta metric (3.0 on the T-score metric)

The PROMIS Bank v1.0 – Depression (recommended) measure uses the following stopping rules:

- Minimum number of items administered = 4
- Stop when one of these occurs:
  - 8 items are administered OR
  - Standard error is below 0.3 on the theta metric (3.0 on the T-score metric) OR
  - Standard error changes by less than 0.01 on the theta metric (0.1 on the T-score metric)

The PROMIS Bank v1.0 – Depression (screen-to-CAT) measure uses the following stopping rules:

- If the response to the first item is the “healthiest” response, then stop.
- If the response to the first item is NOT the “healthiest” response, proceed with the “recommended” CAT stopping rules.

Pediatric and Parent Proxy

For Depression, v2.0 Pediatric and Parent Proxy measures replaced v1.0/v1.1. The v2.0 measures 1) changed from using response scores of 0-4 to use 1-5 (item IDs amended with an “r”) and 2) added new items (item IDs start with 7000). The calibrations between v1.0, v1.1, and v2.0 are identical. The pediatric and parent proxy v1.1 item bank existed briefly – they eliminated one item from the original v1.0 banks. This affected the 8-item short forms as well; the v1.0 and v1.1 short forms have slightly different items included. The v1.1 short form 8b and v2.0 short form 8a include the same items but have different response scores.

**Standard, Recommended, and Screen-to-CAT Stopping Rules:** The standard, recommended, and screen-to-CAT Pediatric and Parent Proxy Depressive Symptoms computer adaptive tests are based on the exact same item banks, but utilize different stopping rules. The PROMIS Pediatric Bank v2.0 – Depressive Symptoms and PROMIS Parent Proxy Bank v2.0 – Depressive Symptoms measures are administered by default as computer adaptive tests using the following standard stopping rules:

- Minimum number of items administered = 5
- Stop when one of these occurs:
  - 12 items are administered OR
  - Standard error is below 0.4 on the theta metric (4.0 on the T-score metric)

The PROMIS Pediatric Bank v2.0 – Depressive Symptoms (recommended) and PROMIS Parent Proxy Bank v2.0 – Depressive Symptoms (recommended) measures use the following stopping rules:

- Minimum number of items administered = 5
- Stop when one of these occurs:
o 12 items are administered OR
o Standard error is below 0.4 on the theta metric (4.0 on the T-score metric) OR
o Standard error changes by less than 0.01 on the theta metric (0.1 on the T-score metric)

The PROMIS Pediatric Bank v2.0 – Depressive Symptoms (screen-to-CAT) and PROMIS Parent Proxy Bank v2.0 – Depressive Symptoms (screen-to-CAT) measures use the following stopping rules:

- If the responses to the first two items are both the “healthiest” responses then stop.
- If the responses to the first two items are NOT the “healthiest” responses, proceed with the “recommended” CAT stopping rules.

SHORT FORMS DIFFERENCES

Adult Profile Short Forms
You will notice that there are 4 depression short forms for adults. Items in the 4a, 6a, and 8a short forms were selected based on rankings using two psychometric criteria: 1) maximum interval information; and 2) CAT simulations. Item rankings were similar for both criteria. For the maximum interval criterion, each item information function was integrated (without weighting) for the interval from the mean to 2 SDs worse than the mean. For the CAT simulations, responses to all items in each bank were generated using a random sample of 1,000 simulees drawn separately for each bank (centered on 0.5 SD worse than the general population mean). Items were rank ordered based on their average administration rank over the simulees. Content experts reviewed the items and rankings and made cuts of 4, 6, and 8 items. For each domain, 4-item, 6-item, and 8-items have been selected so that the items are nested/overlap (e.g., the 8-item form is the 6-item form plus two additional items). The 4a, 6a, and 8a short forms can be administered with short forms of similar length from other domains (anxiety, pain interference, fatigue, sleep disturbance, ability to participate in social roles and activities (v2.0), and physical function (6b and 8b NOT 6a and 8a)) as part of a PROMIS Profile (see PROMIS-29, 43 or 57 Profile v2.0), though they can also be administered individually.

The original adult short form (8b) was constructed by the domain team with a focus on representing the range of the trait and also representing the content of the item bank. Domain experts reviewed short forms to give input on the relevance of each item. Each domain group worked independently and the original short forms are 6-10 items long depending on the domain. Psychometric properties and clinical input were both used and likely varied in importance across domains.

Pediatric and Parent Proxy Short Forms
There is 1 pediatric and 1 parent proxy short form. Items were selected based on content and psychometric characteristics.

Selecting a Short Form
In selecting between short forms, the difference is instrument length. The reliability and precision of the short forms within a domain is highly similar. If you are working with a sample in which you want the most precise measure, select the longest short form. If you have little room for additional measures but really wanted to capture something as a secondary outcome, select one of the shorter instruments (e.g., 4-item short form).

Early Childhood Parent-Report Forms
There are two PROMIS Early Childhood Parent-Report short forms. Items in the 4a and 8a short forms were selected based on content coverage of the key domain facets and psychometric characteristics. The 4-item and 8-item have been selected so that the items are nested/overlap (i.e., the 8-item is the 4-item form plus 4 additional items).
**Recommended Early Childhood Parent-Report Short Form**
The primary difference between the two Early Childhood Parent-Report depressive symptoms short forms is instrument length. The reliability and precision of the short forms within a domain is highly similar. If you are working with a sample in which you want the most precise measure, select the 8-item form. The 8-item form is also superior for individual evaluation/comparing small groups. If you have little room for additional measures but still want to capture the domain, select the 4-item form. Either form is sufficient for large group comparison.

**Parent Proxy Report Versus Early Childhood Parent-Report Measures**
The PROMIS Parent Proxy measures are for parents to report on their children ages 5-17. The PROMIS Early Childhood Parent-Report measures are for parents to report on their children ages 1 to 5. In both cases, the parent provides his or her perspective about the child’s depressive symptoms. Scores from PROMIS Parent Proxy and PROMIS Early Childhood Parent-Report measures are calibrated and normed with different, age-appropriate reference populations and therefore are on different metrics. Scores from one should not be compared to scores on the other. For parents of 5-year-old children, either the PROMIS Parent Proxy or the PROMIS Early Childhood Parent-Report measure can be used. In general, for longitudinal research and/or on-going clinical follow-up, using the measure that aligns with the majority of the time frame with which the child will be studied is recommended. For example, if the measure is administered at child age 1 year through child age 5, using the PROMIS Early Childhood Parent-Report is recommended. If the child will be studied across in both early childhood and beyond age 5, switching to the PROMIS Parent Proxy measure is necessary.

**PROMIS ADULT CANCER MEASURES**
PROMIS-Cancer (PROMIS-Ca) measures (Physical Function, Fatigue, Pain Interference, Depression and Anxiety) were developed under the PROMIS Cancer Supplement (CaPS) grant from NCI. The measures are highly similar to PROMIS measures. Some banks include unique items. In rare instances, a shared item uses different item-level calibrations in each bank.

- **PROMIS-Ca Bank v1.1 - Physical Function** contains 45 items, 33 of which are also in PROMIS Bank v2.0 - Physical Function.
- **PROMIS-Ca Bank v1.0 - Fatigue** contains 54 items, all of which are from PROMIS Bank v1.0 - Fatigue.
- **PROMIS-Ca Bank v1.0 - Anxiety** contains 22 items; 20 items from PROMIS Bank v1.0 - Anxiety, and 2 items unique to CaPS in which cancer specific calibrations were used: EDANX09 & EDANX39.
- **PROMIS-Ca Bank v1.0 - Depression item bank contains 30 items; 23 items are from PROMIS Bank v1.0 - Depression and 7 items unique to CaPS in which cancer specific calibrations were used: EDANG09, EDANG29, EDDEP02, EDDEP12, EDDEP16, EDDEP38 & EDDEP55.
- **PROMIS-Ca Bank v1.1 - Pain Interference** contains 35 items; 32 items from PROMIS Bank v1.1 - Pain Interference v1.1 and 3 items unique to CaPS in which cancer specific calibrations were used: PAININ4, PAININ15 & PAININ30.

PROMIS-Cancer (PROMIS-Ca) measures were developed by having content experts review the adult PROMIS item banks for anxiety, depression, fatigue, pain interference, and physical function. Items were selected through expert consensus and informed by focus groups and cognitive interviews with cancer patients. Multidisciplinary clinical input was obtained to ensure content coverage and the relevance of PROMIS items to patients’ cancer and/or cancer treatment experiences. Items’ psychometric properties were reviewed when applicable. Next, calibration testing was conducted with cancer patients with different diagnoses and treatments. Data were analyzed to identify if items performed differently in people with cancer than people with other chronic conditions or in the general population. In most cases, PROMIS calibrations (*PROMIS Wave
1") were retained. In rare cases where differential item functioning was identified, calibrations for that item were revised for when that item is used in the PROMIS-Ca item bank. For items that exist only in a PROMIS-Ca item bank, new calibrations were created by using a fixed parameter linking strategy. This set of calibrations is named “Cancer” in the HealthMeasures Scoring Service.

A fixed parameter linking approach was taken because of the additional analyses that were conducted to evaluate the differences between the PROMIS item bank and the PROMIS-Ca item bank. The measures produce slightly different scores. This difference was determined to be so small that comparing scores from a PROMIS measure and PROMIS-Ca measure is acceptable. Because the PROMIS measures have demonstrated validity across diverse patient populations, are linked with other PRO measures (i.e., PROsetta Stone), and have continued to be improved through item bank expansion (e.g., PROMIS Physical Function item bank v2.0), it is recommended to use the general population PROMIS calibrations when assessing individuals with cancer.

**SELECTING A PEDIATRIC OR PARENT PROXY INSTRUMENT**

In selecting whether to use the pediatric or parent proxy instrument for this domain, it is important to consider both the population and the domain which you are studying. Pediatric self-report should be considered the standard for measuring patient-reported outcomes among children. However, circumstances exist when the child is too young, cognitively impaired, or too ill to complete a patient-reported outcome instrument. While information derived from self-report and proxy-report is not equivalent, it is optimal to assess both the child and the parent since their perspectives may be independently related to healthcare utilization, risk factors, and quality of care.

**WHICH CALIBRATION SAMPLE SHOULD I USE?**

Some PROMIS Parent Proxy instruments (Anxiety, Depressive Symptoms, Fatigue, Mobility, Pain Interference, Peer Relationships) have two calibration samples – “Parent Proxy” and “Parent Proxy Without Local Dependence.” The former (Parent Proxy) includes calibrations for all items. This is the default calibration sample. If you aren’t sure which calibration sample to use, utilize this one. The Parent Proxy Without Local Dependence does not include calibrations for some items. The items without calibrations are enemy items. That is, a dyad or triad of items was identified in which there are psychometric reasons to only administer one of those items to a given respondent. For example, item Pf2depr11 and Pf2depr3 are enemy items. A participant should only see one of these items in a CAT.

**SCORES**

For most PROMIS instruments, a score of 50 is the average for the United States general population with a standard deviation of 10 because calibration testing was performed on a large sample of the general population. You can read more about the calibration and centering samples on HealthMeasures.net (http://www.healthmeasures.net/score-and-interpret/interpret-scores/promis). The T-score is provided with an error term (Standard Error or SE). The Standard Error is a statistical measure of variance and represents the “margin of error” for the T-score.

**Important:** A higher PROMIS T-score represents more of the concept being measured. For negatively-worded concepts like depression, a T-score of 60 is one SD worse than average. By comparison, a depression T-score of 40 is one SD better than average.
STATISTICAL CHARACTERISTICS

There are four key features of the score for depression:

- **Reliability:** The degree to which a measure is free of error. It can be estimated by the internal consistency of the responses to the measure, or by correlating total scores on the measure from two time points when there has been no true change in what is being measured (for z-scores, reliability = 1 – SE²).

- **Precision:** The consistency of the estimated score (reciprocal of error variance).

- **Information:** The precision of an item or multiple items at different levels of the underlying continuum (for z-scores, information = 1/SE²).

- **Standard Error (SE):** The possible range of the actual final score based upon the scaled T-score. For example, with a T-score of 52 and a SE of 2, the 95% confidence interval around the actual final score ranges from 48.1 to 55.9 (T-score ± (1.96*SE) = 52 ± 3.9 = 48.1 to 55.9).

The final score is represented by the T-score, a standardized score with a mean of 50 and a standard deviation (SD) of 10.

In Figure 2 (Adult 8b short form), the two dotted horizontal lines each represent a degree of internal consistency reliability (i.e., .90 or .95) typically regarded as sufficient for an accurate individual score. The shaded blue region marks the range of the scale where measurement precision is comparable to the reliability of .90 for the eight-item form. Figure 2 also tells us where on the scale the form is most informative based upon the T-score. This form would typically be more informative than a depression form with fewer items.

The three dotted horizontal lines in Figure 3 each represent a degree of internal consistency reliability (i.e., .70, .90, or 0.95) typically regarded as sufficient for an accurate individual score for the Early Childhood Parent-Report item bank. The shaded blue region marks the range of the scale where measurement precision is comparable to the reliability of .70 for the form.

Figure 4 (Adult 4a, 6a & 8a short forms) also tells us where on the scale the form is most informative based upon the T-score: the 8-item form is more informative than the 6-item form, which is more informative than the 4-item form. See additional test information figures for pediatric instruments in Appendix 1.

Figure 5 is a sample of the statistical information available for the Adult Depression CAT.

More information is available on HealthMeasures.net.
PREVIEW OF SAMPLE ITEM

Figure 6 is an excerpt from the paper version of the adult eight-item short form. This is the paper version format used for all depression instruments. It is important to note that the CAT is not available for paper administration, though PDFs are available to review all included items.

FREQUENTLY ASKED QUESTIONS (FAQs)

Q: I am interested in learning more. Where can I do that?
Review the HealthMeasures website at [www.healthmeasures.net](http://www.healthmeasures.net).

Q: Are these instruments available in other languages?

Q: Can I make my own short form?
Yes, custom short forms can be made by selecting any items from an item bank. This can be scored using the Scoring Service ([https://www.assessmentcenter.net/ac_scoringservice](https://www.assessmentcenter.net/ac_scoringservice)).
APPENDIX 1

Figure 5 – Pediatric Test Information Depression
